To trade trapped positions at high volume nodes, you need to wait for the price to return to the high volume cluster where these traders are based and then look for a specific, volume-backed entry signal 1, 2.

Here is the step-by-step strategy for executing this trade:

- **Wait for the trigger signal:** Watch for the price to sweep back to the edge of the high volume node 2. At this edge, you need to look for a specific candle model, such as a **doji, hammer, or shooting star** 2, 3.
- **Confirm the volume:** This trigger candle must have **relatively higher volume** than the preceding candle in the direction of your trade 2, 3.
- **Wait for the candle to close:** You must let the candle fully close to confirm the volume spike. **Never front-run the signal** 3.
- **Enter the trade and place your stop:** Once the closed candle and volume spike are confirmed, enter your position (e.g., go long) 3. Place your stop loss **just below the node** 3. If the price falls through and takes out the node, your trading thesis is dead 3.
- **Set your target:** Your profit target should be the **opposite edge of the profile**, allowing you to play the trade "edge to edge" 3.
